Summary

Current global changes negatively impact insect pollinators, which directly impacts the pollination of wild and domesticated flowering plants and the functioning of ecosystems. Amongst these threats, many synergistic drivers, such as habitat destruction and fragmentation, increasing use of agrochemicals, decreasing resource diversity, as well as climate change, are known to affect wild and managed bees. All these drivers potentially have a direct or indirect impact on the nutritional quality of pollen collected by female bees to feed their larvae. This report contains an extensive dataset of the chemical composition of pollen collected by the European honeybee (*Apis mellifera*), the buff-tailed bumble bee (*Bombus terrestris*), and the red mason bee (*Osmia bicornis*) sampled at 128 sites across eight European countries in landscape gradients dominated by two major bee-pollinated crops (apple and oilseed rape). The data offer the opportunity to test whether variation in the nutritional quality of pollen diet is structured by species-specific traits, environmental factors, and/or drivers of global change. We show that the bees were able to collect resources of similar chemical qualities in the 8 countries. We also show that the three species collected resources of similar values in terms of total protein concentration but different lipid concentration. These preliminary results confirm the hypothesis of interspecific variation in nutritional requirement of bees.

1. Introduction

Losses and declines in managed and wild bee populations have been reported worldwide (Cameron *et al.*, 2011; Goulson *et al.*, 2015; Duchenne *et al.*, 2020). Habitat loss and agricultural intensification, resulting in landscape simplification, have been identified as important drivers of pollinator decline (Winfree, 2010; Vray *et al.*, 2019). These factors can directly or indirectly affect the quality, quantity and the diversity of floral resources and thus the food sources of bees (e.g. Roger *et al.*, 2017b). This makes the abundance, distribution/availability, quality and diversity of these resources potentially the main proximal pressure explaining bee population trends (Roulston & Goodell, 2011).

Chemical composition of pollen is very complex and highly diverse among flowering plants (Carnell *et al.*, 2020; Table 1). Bees obtain their carbohydrate nutrient intake mainly from nectar, but their protein and lipid from pollen (Human & Nicolson, 2006; Roulston & Cane, 2000). The chemical composition of pollen is also highly variable in these two compounds, between 2-60% and 1-20% for protein and lipid contents, respectively (Roulston & Cane, 2000; Carnell *et al.*, 2020; (Vaudo *et al.*, 2020) (Table 1). Field and semi-field studies showed that this chemical composition can be related to bee health (e.g., honey bee *A. mellifera*: Alaux *et al.* (2010); di Pasquale *et al.*, (2013); mason bee *Osmia bicornis*: Bukovinszky *et al.* (2017)). Generalist bees seem able to assess pollen chemical quality and balance multiple macronutrient resources when making foraging decisions (Vaudo *et al.*, 2016; Kraus *et al.*, 2019). Based on a large quantity and diversity of samples, Vaudo *et al.* (2020) showed that honey bees collected pollen between 1:1 and 2:1 protein to lipid (P:L) ratios. This species appears to occupy a different nutritional space compared to *Bombus impatiens* and *Osmia cornifrons*, which collect at a P:L ratio of 4:1. Furthermore, to satisfy the food intake of colonies with numerous individuals, honey bees must collect large amounts of pollen. Therefore, honey bees collect pollen from generalist, open floral morphologies such as mass blooming trees (e.g. *Quercus* sp., *Salix* sp., *Prunus* sp.) and wild herbs with high production of pollen (e.g. Asteraceae,), which may have a nutritional make up that falls in the lower P:L values (i.e. 1-3:1 P:L) (Vaudo *et al.*, 2020). Bumble bees appear much more picky in their choices, many species mainly forage on Fabaceae pollen showing a high P:L ratio value (3.8 ± 0.5) (Leonhardt & Blüthgen, 2012). In contrast to honey bees and bumble bees, *Osmia cornifrons*, a solitary foraging bee with a short flight period, has mixed preferences for Rosaceae and Fabaceae pollen ((Haider *et al.*, 2014)). Interestingly, the average P:L ratios of Rosaceae (1.6 ± 0.3 P:L) and Fabaceae

($3.8 \pm 0.5\text{P:L}$) are similar to the average P:L value preferred by *O. cornifrons* ($\sim 2.9\text{ P:L}$)(Vaudo *et al.*, 2020).

Regarding chemical profiles, particular lipids and proteins seem more important to bee nutritional requirements. For example, sterols (e.g. β -sitosterol) are essential to synthesise ecdysteroid, which is involved in larval moulting and the maturation of the ovaries in adult females. In the case of sterol deficiency, a delay in moulting can be observed (Regali, 1996). Additionally, a good amino acid balance is crucial for the bee development (Moerman *et al.*, 2017). Amino acids are involved in growth, survival, flight ability, and immunity (Carter *et al.*, 2006; Moerman *et al.*, 2017; Regali, 1996; Roger *et al.*, 2017a). Some amino acids (methionine, lysine, threonine, histidine, leucine, isoleucine, valine, phenylalanine, tryptophan) and sterols (24-methylenecholesterol and β -sitosterol) cannot be synthesised by bees and are therefore considered as essential, meaning that it is necessary to obtain them through pollen consumption (de Groot, 1953).

Experimental studies in controlled conditions have confirmed that the nutritional quality of pollen (e.g., the concentration of protein and lipids) can have an impact on the development and mortality of bumble bees (e.g. Barraud *et al.*, 2020; Carnell *et al.*, 2020; Moerman *et al.*, 2017; Vanderplanck *et al.*, 2014) and mason bees (Eckhardt *et al.*, 2014; Sedivy *et al.*, 2011). The floral diversity of pollen diets does not seem to be the major factor of quality, as bumble bees develop better on high-quality monofloral diets compared to low-quality polyfloral diets (Moerman *et al.*, 2017; Carnell, Hulse and Hughes, 2020). The pattern for honey bees appears to be similar at an individual level, with pollen quality (reflected by protein content) having an impact on the physiology and survival of adult honey bees (Brodschneider and Crailsheim, 2010; Di Pasquale *et al.*, 2013; Frias *et al.* 2016).

Overall, these results suggest that a loss of a part of the plant community, especially the families covering specific physiological requirement (i.e., Fabaceae), is more likely to affect bumble bees and solitary bees than honey bees (Leonhardt & Blüthgen, 2012). The more generalised the foraging behaviour of a particular bee species, the more likely it is to be able to switch to alternative host plants and persist in an area, even if those host plants are of a lower nutritional quality (Roger *et al.*, 2017b). However, there are very few studies evaluating and comparing the development of various generalist bee species in controlled conditions on the same pollen diets (Moerman *et al.*, 2017), and no study considering a broad diversity of bee clades (e.g. different bee tribes or bee families) in field conditions.

Table 1. Chemical components of pollen (updated from Carnell *et al.* 2020)

Components	Examples	Natural variation in the wild	Can be detected by bees?	Main references
Proteins	Enzymes (e.g. oxidases, lyases, ...)	2-60%	YES	Roulston and Cane (2000); Vaudo <i>et al.</i> (2020)
Amino acids	Proline, glutamine, tryptophan	All or most are present, <2% each	YES	Carter <i>et al.</i> 1999; Roger <i>et al.</i> (2017a)
Lipids	Fatty acids	1-20%	YES	Vaudo <i>et al.</i> (2020)
Sterols	β -sitosterol	Highly variable	YES	Vanderplanck <i>et al.</i> (2011)
Specialised metabolites	Alkaloids, phenolics, tanins	Highly variable	YES	Gosselin <i>et al.</i> (2013); Wang <i>et al.</i> , 2019

The present study reports results from the analyses of pollen collected by three species of commercially produced ‘sentinel’ bees (*Apis mellifera*, *Bombus terrestris* and *Osmia bicornis*) within two mass-flowering crops, apples and oilseed rape, in eight countries: Ireland, UK, Spain, Germany, Sweden, Estonia, Switzerland and Italy. This report is a part of a global study aiming to gain a holistic picture of the multiple environmental and biotic stressors encountered by bees occurring in

representative agricultural landscapes in each of the participating countries. To meet this aim a full suite of measurements was planned to encapsulate the variation in habitat quality, the abundance of flowering plants, the diversity of chemical pollutants present on the bees themselves and in their food resources, and the frequency and co-occurrence of colony pests and pathogens, that bees encountered under typical field conditions.

2. Methodology

2.1 Overview of the study

This study was carried out in the framework of the Horizon 2020 project PoshBee (<http://poshbee.eu>), which aims to support healthy bee populations, sustainable beekeeping and pollination in Europe. The goal of Work Package 1 (WP1) is described as “developing a site network for assessing exposure of bees to chemical, nutritional, and pathogen stressors” and led by Trinity College Dublin (Ireland). WP1 also includes 30 additional collaborators across 14 European countries (<http://poshbee.eu/partners>). The goal of PoshBee Work Package 2 (WP2) is described as “measuring chemical exposure, pathogens and aspects of nutrition in honey bees, bumble bees and solitary bees” and is led by the *Agence Nationale de la Sécurité Sanitaire de l'alimentation, de l'environnement et du travail* (ANSES, France). WP2 also includes seven additional beneficiaries across five countries. Apple orchard sites and winter-sown oilseed rape sites were selected according to a gradient of land-use intensity in each of eight countries chosen to represent four major European biogeographical areas: Boreal (Sweden and Estonia), Atlantic (Ireland and United Kingdom), Continental (Germany and Switzerland) and Mediterranean (Spain and Italy). These two crops show contrasting growing systems and pollination biology: apple (*Malus domestica*), a perennial, self-incompatible crop grown in long standing (5-10 year) orchard plantations and winter-sown oilseed rape (*Brassica napus*), an annual, self-compatible crop planted irregularly as a break crop in arable rotations. There were eight sampling sites for each type of crop in each country. Thus, a total of 128 sites were selected along a gradient of land use intensity (see Vanderplanck *et al.* (2021) for dataset on landcover and management). All sites were surveyed using the same methods as part of the European Union PoshBee project (<http://poshbee.eu>), standardised following the PoshBee protocols (Hodge & Stout, 2019).

2.2 Collection and preparation of pollen samples

Three honeybee hives (*A. mellifera*), three *B. terrestris* colonies and 3 nest boxes (each with 100 cocoons) of *O. bicornis* were placed in each site (except for *Osmia*, see table 2) and standardised following internal PoshBee protocols (Hodge and Stout 2019). *Apis mellifera* colonies were provided by local suppliers, representing local races (Hodge *et al.*, in prep; Table 2 for details about the honey bee subspecies). All bumble bee colonies were purchased from local suppliers, and represented the local wild subspecies. For 6 of the 8 countries this was a single continental *B. terrestris* population, but for Ireland and the UK it was a single *B. terrestris audax* population. All *Osmia* cocoons were provided by Wildbiene & Partner (Switzerland) at no cost to the project.

Table 2. Summary of species and subspecies used in the different countries. APP = Apple trees, OSR = Oil-seed rape.

COUNTRIES	<i>Apis mellifera</i> subspecies	<i>Bombus terrestris</i> subspecies	<i>Osmia bicornis</i>
Estonia (EST)	<i>A. m. ligustica</i>	<i>B. t. terrestris</i>	<i>O. bicornis</i>
Germany (GER)	APP: <i>A. m. carnica</i> OSR: <i>A. m. mellifera</i>	<i>B. t. terrestris</i> <i>B. t. terrestris</i>	<i>O. bicornis</i> <i>O. bicornis</i>
Great Britain (GBR)	APP: <i>A. m. mixed</i> OSR: <i>A. m. buckfast</i>	<i>B. t. audax</i> <i>B. t. audax</i>	None None
Ireland (IRL)	<i>A. m. mellifera</i>	<i>B. t. audax</i>	None
Italy (ITA)	<i>A. m. ligustica</i>	<i>B. t. terrestris</i>	<i>O. bicornis</i>
Switzerland (CHE)	<i>A. m. carnica</i>	<i>B. t. terrestris</i>	<i>O. bicornis</i>
Spain (ESP)	<i>A. m. iberiensis</i>	<i>B. t. terrestris</i>	<i>O. bicornis</i>
Sweden (SWE)	<i>A. m. mixed</i>	<i>B. t. terrestris</i>	<i>O. bicornis</i>

Pollen bread from nests were collected around the peak of the flowering season of the focal crop. Pollen bread from western honey bees were collected in the *Apis* hives (Fig. 1A). Pollen bread from bumble bees were collected in the bumblebee colony (Fig. 1B). Pollen from *Osmia* was collected from 10 nest tubes before the larvae ate all the stored pollen (Fig. 1C). Overall we aimed to collect 384 pollen samples (8 countries, 2 crops, 8 sites, 3 species).

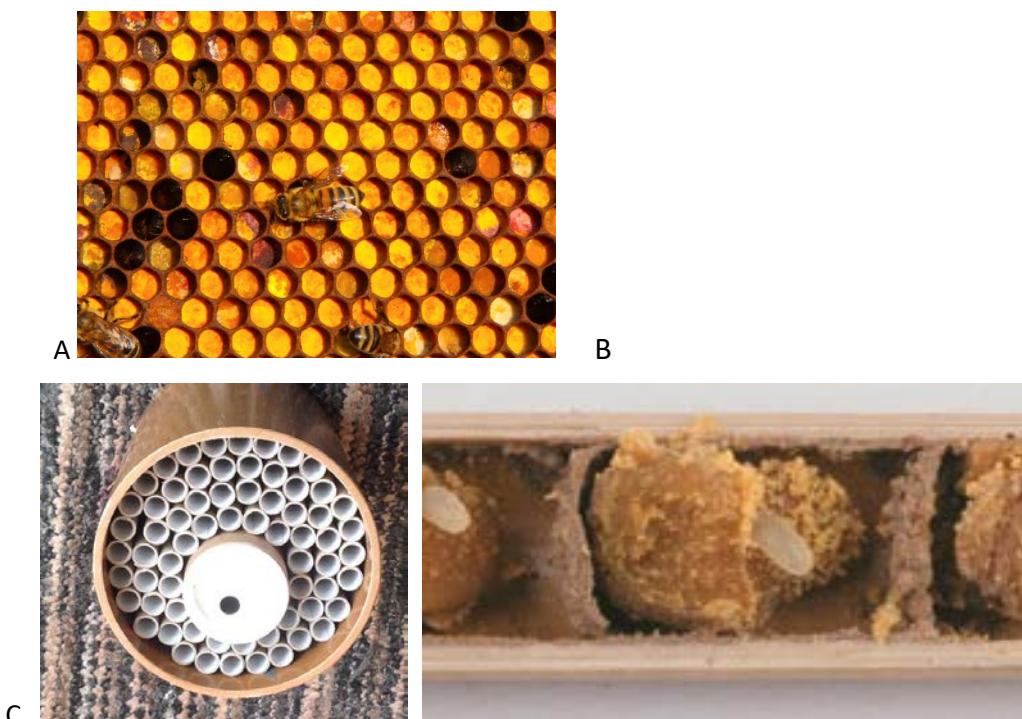

Figure 1. Nest and device to collect pollen. A. Pollen stored in honey bee hive. B. Bumble bee colony with queen and workers. C. *Osmia bicornis* nest with the central chambers loaded with cocoons and a view in the nest with pollen

All samples were weighed before freezing at -20°C. Sample homogenization was conducted by PIWET before preparing sub-samples for palynological (CREA) and chemical analyses (UMONS). Thanks to homogenization, all analyses are related to exactly the same samples of pollen bread (or pollen loads) and the results obtained from their analysis complement each other.

2.3 Sample analyses

Nutrition was evaluated based on beebread from the nests of honey bees, bumble bees and solitary bees from the site network (WP1). Nutritional aspects were addressed through the identification of botanical origin of pollen and the characterisation of total protein, total lipid, and total glucid (Table S1). Analyses of amino acids (total concentration, essential amino acid concentration and global profile) and sterols (total concentration and global profile) were challenged by the Covid pandemic in terms of access to the laboratory and late delivery of some analytical material. These are still running (Table S2).

2.3.1 Protein analyses

Pollen protein concentration was measured using the Bradford assay according to Vaudo *et al.* (2020). We added 1.5mL of 0.1M NaOH to ~1mg of pollen sample. We conducted the Bradford assay with the Bio-Rad Protein Assay Kit microassay 300 µL microplate protocol using bovine γ-globulin as the protein standard (Bio-Rad Laboratories, Inc., Hercules, CA). We used three technical replicates for each biological replicate and measured absorbance at 595nm using a SpectraMax 190 spectrophotometer (Molecular Devices, LLC, Sunnyvale, CA). Protein concentrations were calculated using linear regression analysis from the protein standards.

2.3.2 Lipid analyses

Pollen lipid concentrations were determined using a modified protocol from Van Handel and Day (1988). In 2.0mL microcentrifuge tubes, we added 200µL 2% sodium sulfate and 1.6mL chloroform/methanol to ~1mg of each pollen sample before a 5 min centrifugation. Supernatant was transferred to a clean glass tube with 600µL DI water, and centrifuged for 5 min. We separated the top carbohydrate/water/methanol fraction and the remaining chloroform fraction was used for lipid analysis. The lipid/chloroform fraction was left overnight in a fume hood to completely evaporate the solvent. We added 200µL sulfuric acid to the sample and heated at 100°C for 10min. Then, 5mL of vanillin/phosphoric acid reagent was added. We used three 300µL technical replicates for each biological replicate and measured absorbance at 525nm. Lipid concentrations were calculated using linear regression analysis from vegetable oil standards. Pollen concentrations of proteins and lipids are reported as µg nutrient/mg pollen, and subsequent P:L ratios were determined for each diet.

2.3.3 Glucid analyses

For carbohydrate analysis, we heated each sample at 100°C to evaporate the solvent to ~100 µL. We added anthrone/sulfuric acid reagent to bring each sample to 5 mL and heated the samples at 100°C for 17 min. Each sample was removed from the heat and allowed to cool. We used two technical replicates for each biological replicate and measured absorbance at 625 nm using a SpectraMax 190 spectrophotometer (Molecular Devices). Carbohydrate concentrations were calculated using simple linear regression analysis from anhydrous glucose standards using SoftMax Pro v.4.0 software.

2.3.4 Amino acids analyses

For the analysis of total amino acids, 1mL of hydrolysis solution (6N HCl, 0.1% phenol and 500 µM norleucine) was added to 3–5 mg (dry weight) of pollen (Vanderplanck *et al.*, 2014) and then incubated for 24 hours at 110°C. The hydrolysate was evaporated until dryness under vacuum in a boiling bath at 100°C. Afterwards, 1 mL of the sodium citrate buffer pH 2.2 was added into the tube. The sample

solution was poured into an HPLC vial after filtration (0.2 µm filter), and each amino acid was measured separately with an ion-exchange chromatograph. A post-column ninhydrin reaction produced coloured derivatives, which was monitored via a UV detector. For amino acid quantification, norleucine was used as the internal standard. This analysis includes essential amino acids that bees cannot synthesize, as well as the non-essential ones. The essential amino acids were originally determined by de Groot (1953) for honey bees, and they are arginine, histidine, isoleucine, leucine, lysine, methionine, phenylalanine, threonine, tryptophan and valine.

2.3.5 Sterol analyses

Before each analysis, pollen samples were divided into a minimum of three samples (i.e., 20 mg per analytical replicate). Sterols were quantified by GC-FID after extraction and purification according to the method described by Vanderplanck *et al.* (2011). The multi-step procedure can be summarized as follows: (i) saponification with 2M methanolic potassium hydroxide, (ii) extraction of the unsaponifiable portion with diethylether and several water washings, (iii) solvent evaporation, (iv) fractionation of the unsaponifiable portion by TLC, (v) trimethylsilylation of the sterols (scraped from the silicagel) and (vi) separation by GC. The total sterol content was determined considering all peaks above the limit of quantification; LOQ = 9.6 ng/1.2 µl injected whose retention times were between cholesterol and betulin (internal standard). Individual sterols were quantified on the basis of peak areas from analyses. Under the present analytical conditions applied, campesterol and 24-methylenecholesterol co-eluted. Therefore, the results are pooled for these two compounds. Compounds were identified according to their retention times by comparison with those of sunflower oil as reference. The identifications were corroborated by GC-FID (Vanderplanck *et al.*, 2011).

2.4 Data management and analyses

All results available by 17/11/2021 were included in the common data bank of the WP2 results managed by the PoshBee consortium (i.e. Posbase). We present here a simple description of the dataset. Detailed analyses of the data set will be developed in future publications.

3 Results and preliminary discussion

Overall 329 samples were collected and analysed in analytical triplicate when possible (Table S1). We missed 32 samples that were not collected for *Osmia* in two countries (Table 2). Analyses of amino acids and sterols will be partly finished by December 2021 (Table S2).

Values of total protein were quite stable in the 8 countries when considering data aggregation of pollen from *Apis* and *Bombus* in all sites and both crops in the same country (Fig. 2A). The potential access to protein in different agro-ecosystems seems to be quite stable, as mentioned in Roger *et al.* (2017a). On the contrary, values of total lipids and glucids were quite variable among countries and agro-ecosystems (Figs 2B-C).

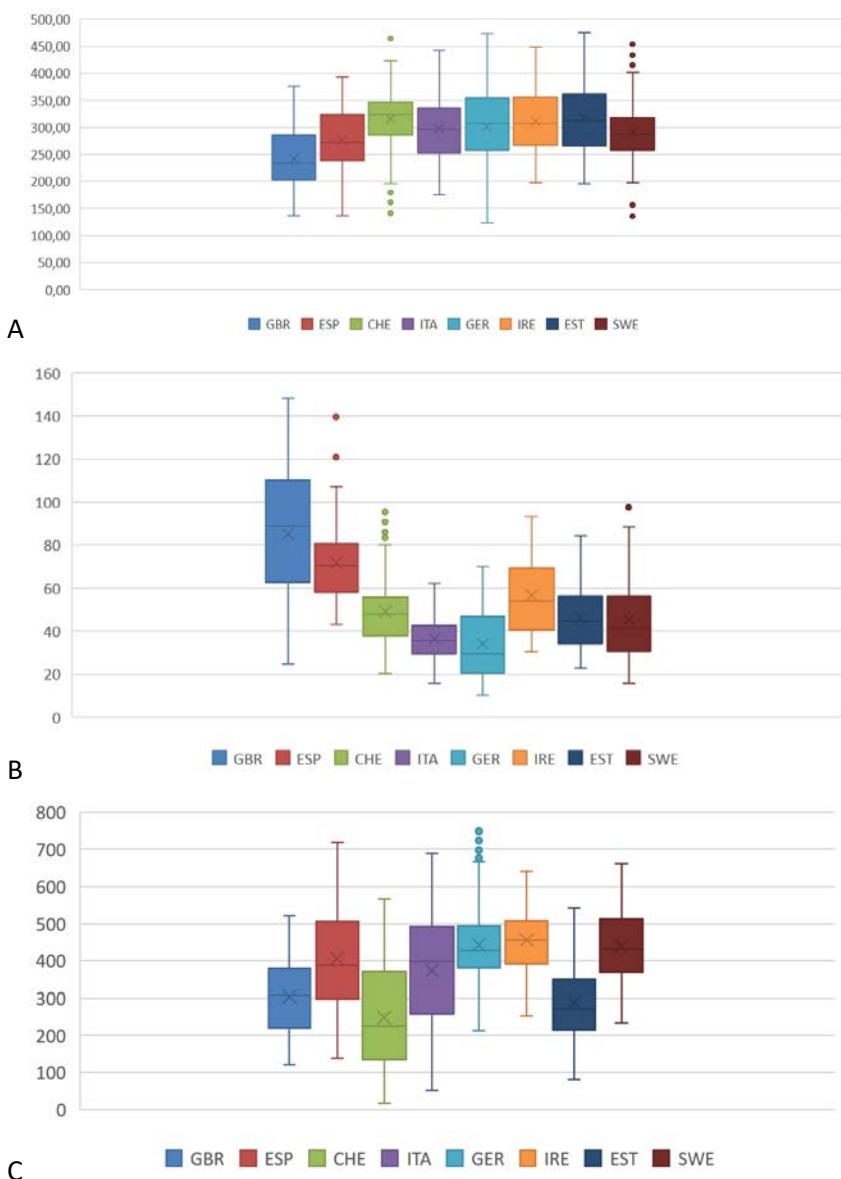

Figure 2. A. Total protein content ($\mu\text{g}/\text{mg}$) average per species per country (aggregation of data from *Apis* and *Bombus*). B. Total lipid content ($\mu\text{g}/\text{mg}$) average per species per country (aggregation of data from *Apis* and *Bombus*). C. Total glucid content ($\mu\text{g}/\text{mg}$) average per species per country (aggregation of data from *Apis* and *Bombus*).

Constancy in protein and glucid values but variation in lipid values was found when we analysed the data at the species level (Figs 3A-C). Moreover, as expected from previous literature, the protein:lipid ratio is twice as low in the diet of *Apis* compared to the diet of *Bombus* (Vaudo *et al.* 2020) even if we considered *Bombus terrestris* instead of *Bombus impatiens*. As floral choices are quite conserved in bumble bees (Wood *et al.* 2021), the nutritional requirement may also be conserved.

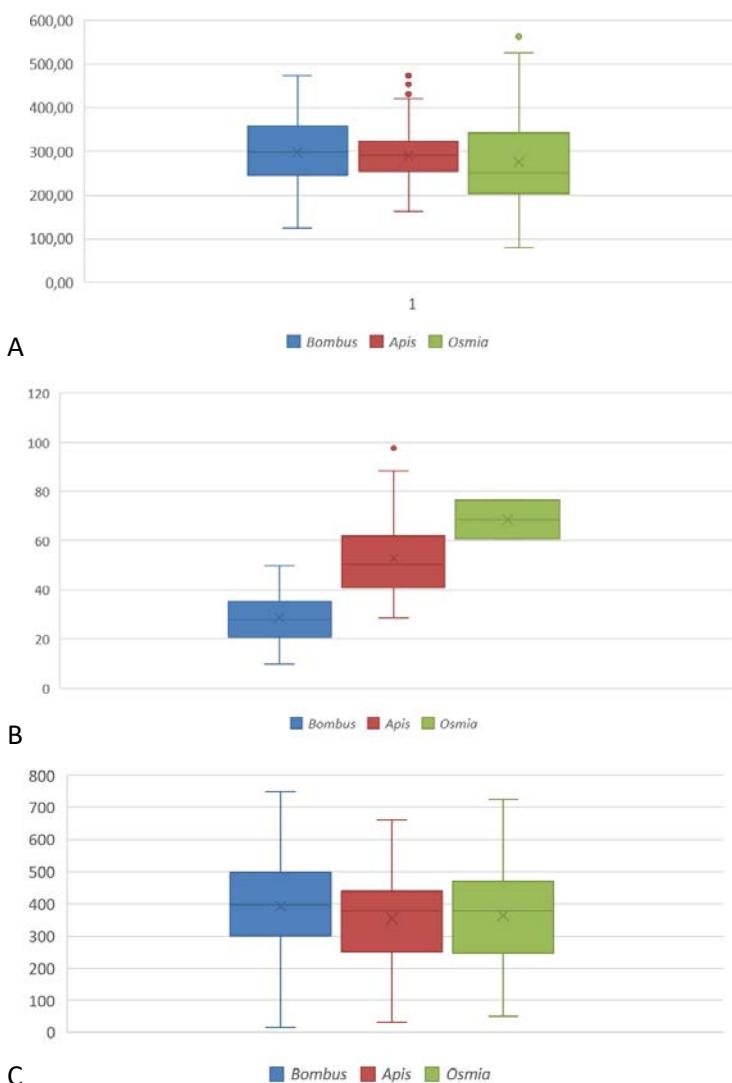

Figure 3. A. Total protein content ($\mu\text{g}/\text{mg}$) average for *Bombus*, *Apis* and *Osmia*. B. Total lipid content ($\mu\text{g}/\text{mg}$) average for *Bombus*, *Apis* and *Osmia*. C. Total glucid content ($\mu\text{g}/\text{mg}$) average for *Bombus*, *Apis* and *Osmia*.

Among the three tested species, the lowest ratio P:L is found for *Osmia*, while it had an intermediate position in the study of Vaudo *et al.* (2020) (i.e. between *Apis* and *Bombus*). This difference might be due to the fact that Vaudo *et al.* (2020) considered *Osmia cornifrons*, while we analysed the pollen diet of *Osmia bicornis*. Floral choices in the genus *Osmia* seem much more variable than in the genus *Bombus* (Praz *et al.*, 2008). This might explain the difference in protein:lipid ratio in the pollen diet of *Osmia cornifrons* and *Osmia bicornis*.
